

Western Lake Erie HAB Early Season Projection

Bulletin 06- 2024-06-06

Summary: The Western Lake Erie HAB Early Season Projection provides an estimate of potential *Microcystis* harmful algal bloom (HAB) severity. The projected severity depends on input of total bioavailable phosphorus (TBP) from the Maumees River during the loading season (Mar. 1-Jul. 31), and uses a combination of measurements (USGS) and forecasts of Maumees River discharge from the National Weather Service - Ohio River Forecast Center (through Jul.) and TBP loads measured by the Heidelberg U. National Center for Water Quality Research.

With observations through June 4 we now predict a potential severity range of 4.5-7. As compared to early spring (March-April), drier, near-normal rainfall conditions have been observed in May and early June and are expected to persist. We continue to expect a moderate to larger-than-moderate summer bloom. If average rainfall is maintained through June and July, we expect a severity closer to 5, similar to the 2023 bloom. If higher than average rainfall occurs, the bloom severity may be higher (~7), closer to 2022.

The range in forecasted severity reflects the uncertainty in forecasting precipitation, particularly through June and July. We will issue a comprehensive seasonal forecast on June 27. Any bloom that does develop will change throughout the summer and move with the wind and currents; we will provide information on the presence and location of the bloom throughout the summer via forecasts that are [posted daily on the web](#), and emailed to subscribers weekly.

- A. Hounshell, C. Owens, R. Stumpf, J. Noel, A. DaSilva (NOAA), & L. Johnson (Heidelberg University)

Predicted Bloom Severity

Fig. 1. Predicted bloom severity as compared to previous years. The wide red bar is the likely range of severity based on the limits of the forecast uncertainty (4.5-7). There is uncertainty in the bloom severity due to the range in estimated Maumees River flow from the river forecast and subsequent TBP loads in June and July.

Cumulative Total Bioavailable Phosphorus

Fig. 2. Cumulative TBP loads for the Maumees River (Waterville, OH). Each line denotes a different year or the min/max cumulative load since 2002. 2024 is in red: the solid line is the measured load to June 4; the red area shows the likely range for the remainder of the loading season; and the light red shows the possible range.

Total Bioavailable Phosphorus

Fig. 3. Total bioavailable phosphorus (TBP) load accumulated from the Maumees River near Waterville, OH to date. The right axis denotes the TBP load from selected previous years.

Satellite Image - True Color

Fig. 4. True color image for 31 May 2024 derived from the Copernicus Sentinel-3a/b satellite. The western basin has less suspended sediment (tan color) and a smaller spring diatom bloom in Maumees and Sandusky Bays (khaki color) than May.
